Results:  $\Omega$  vs  $\Lambda$   
from 6 supernovae

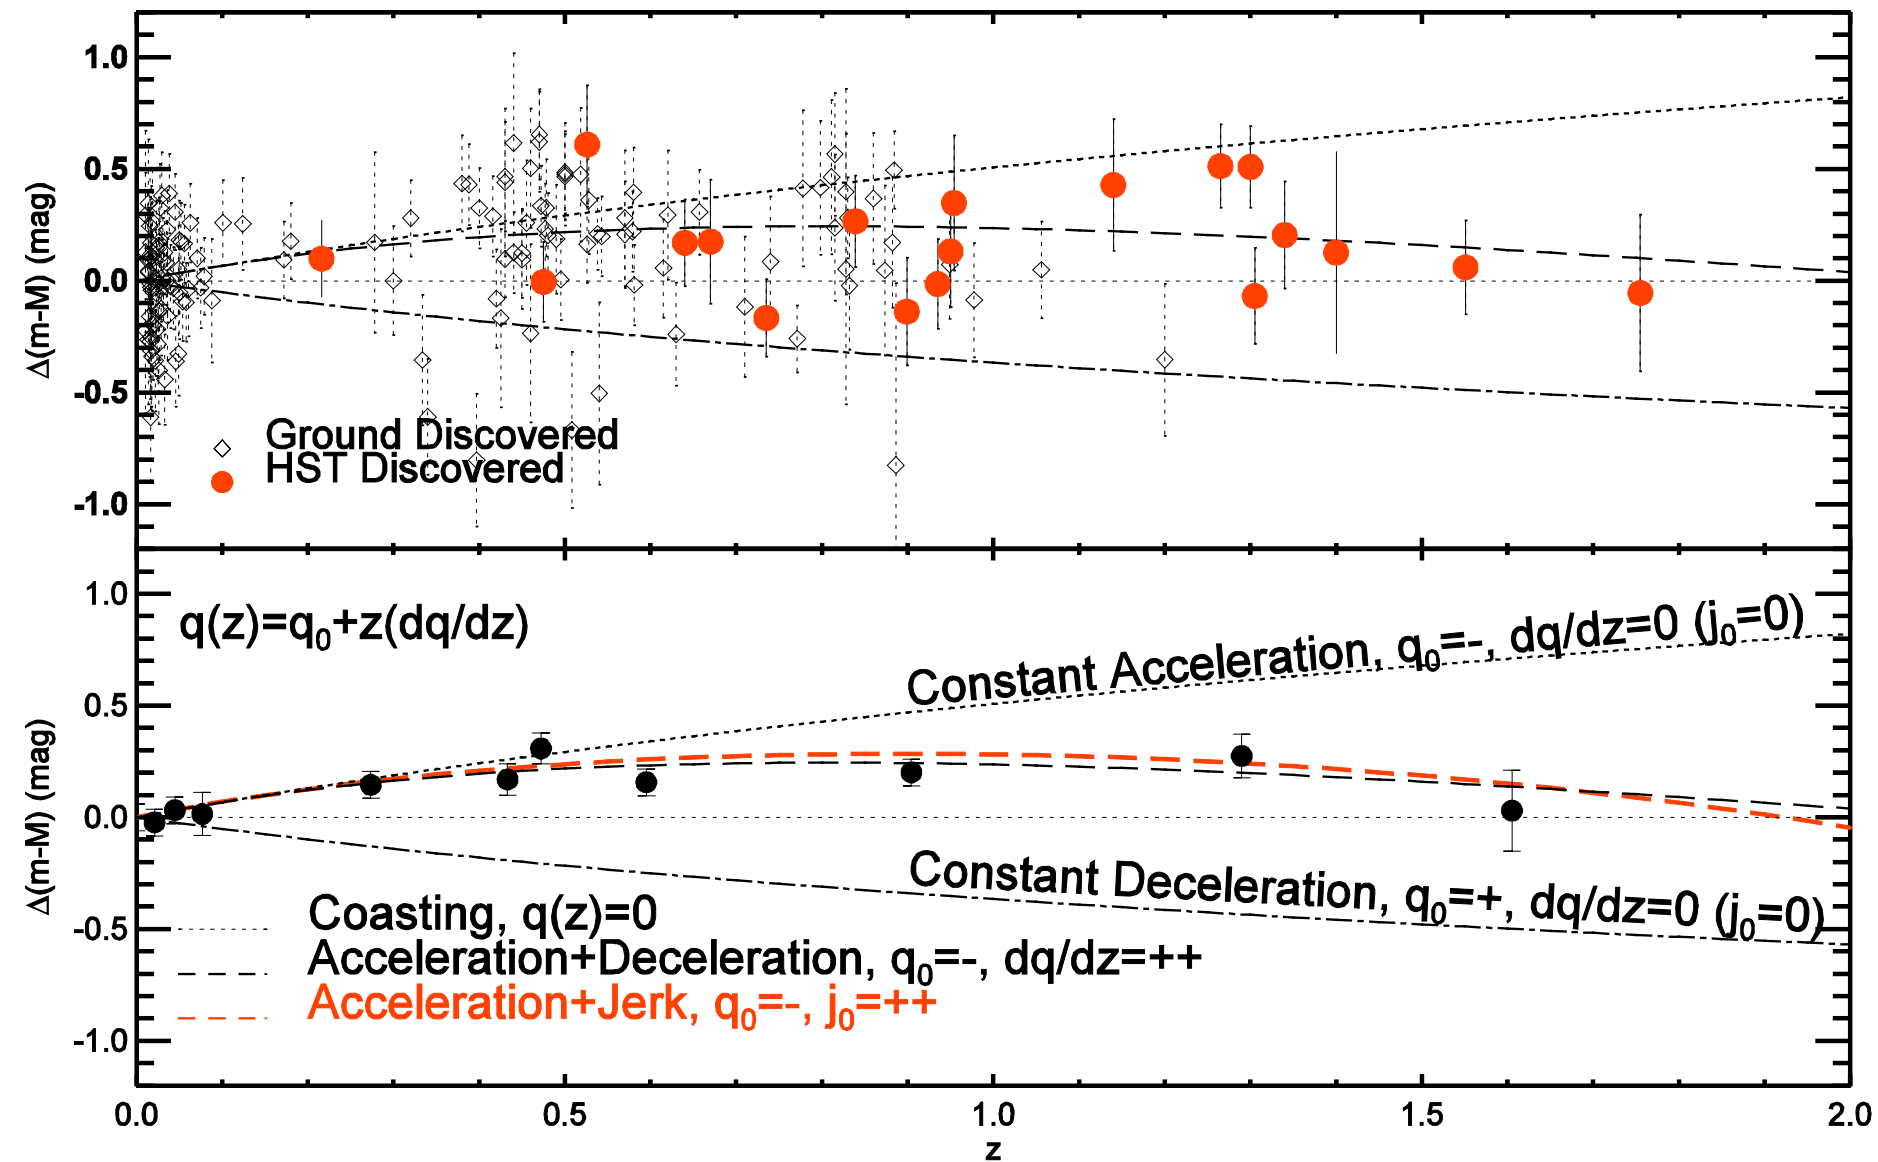

Results:  $\Omega$  vs  $\Lambda$   
from 40 supernovae

Late 1990s

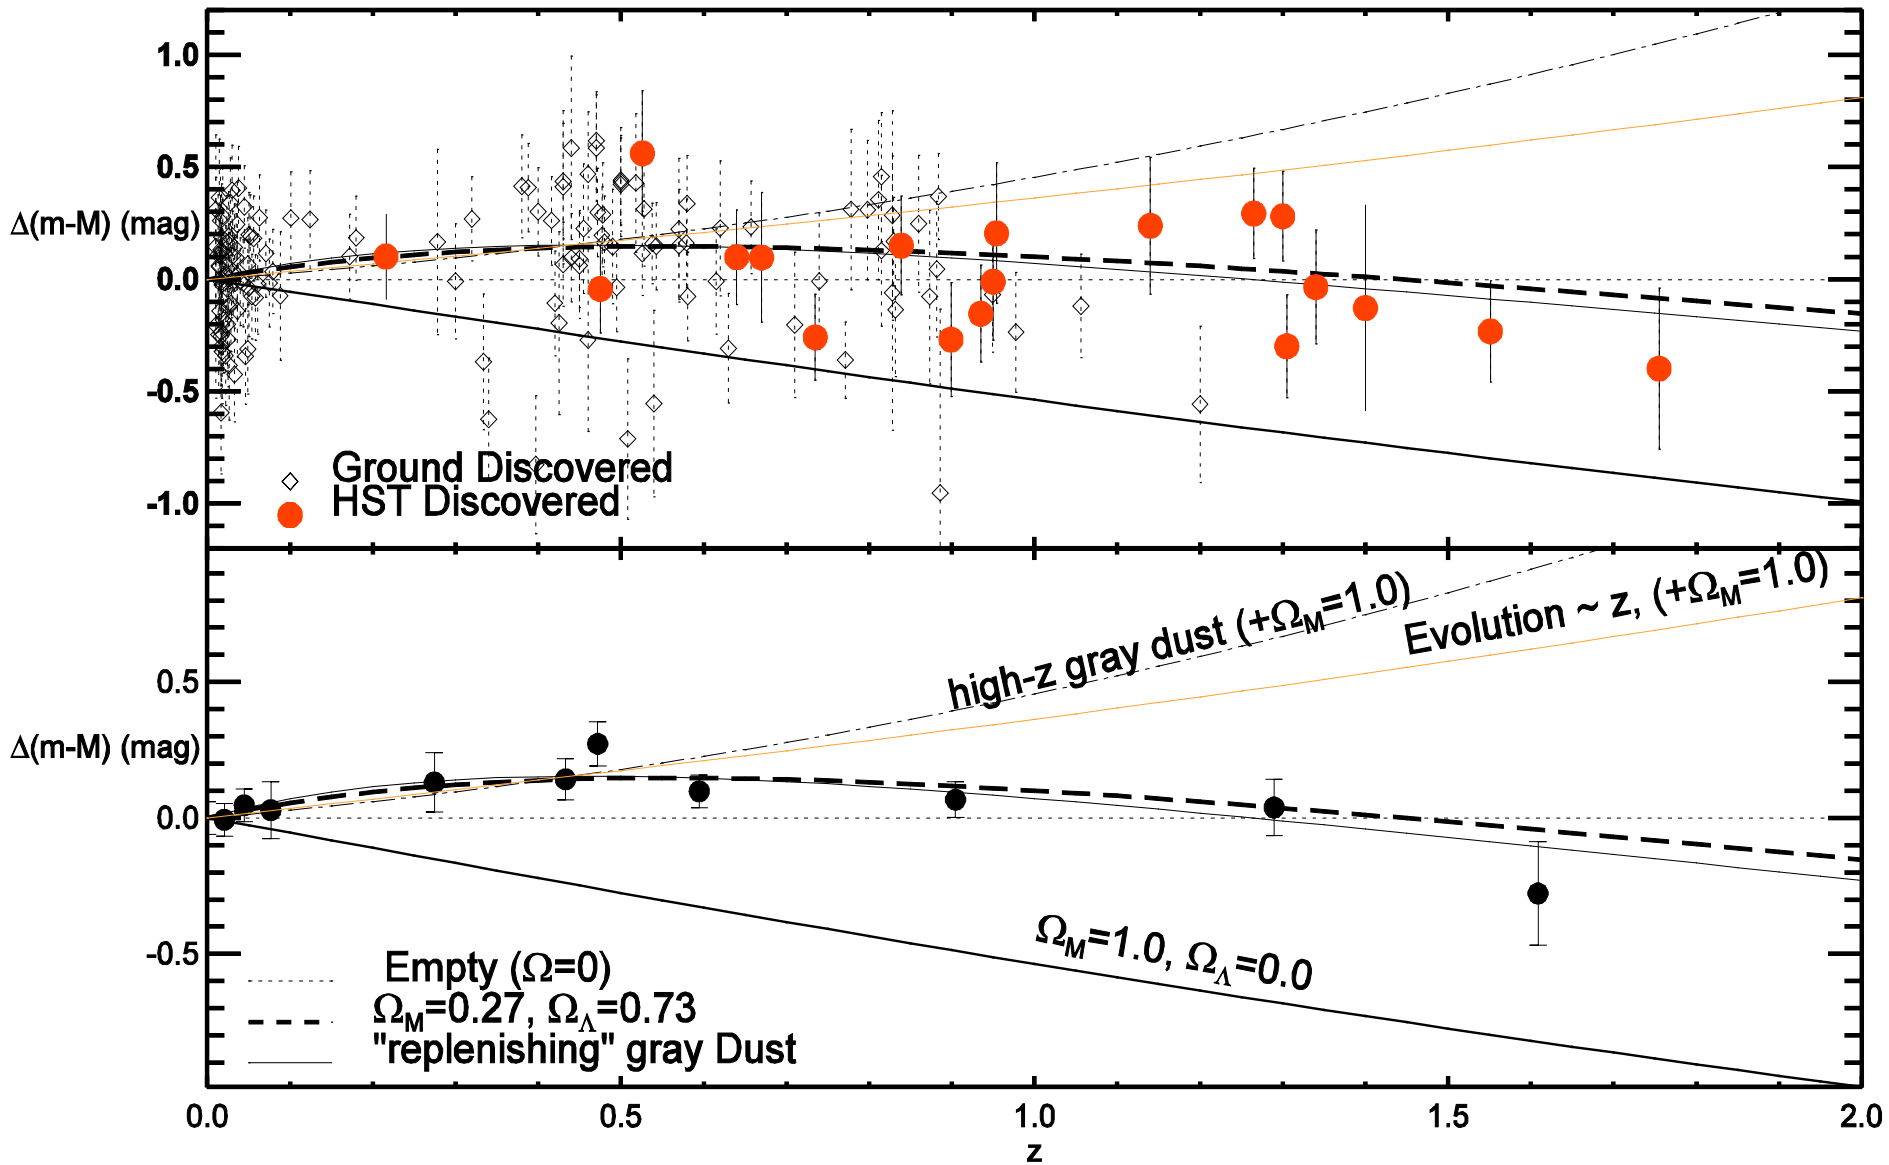

These two plots show the best-fit confidence regions on the  $\Omega_M$ -vs- $\Omega_\Lambda$  plane for the 6-supernova fit presented in the Nature (1998) paper and for a more extensive 40-supernova fit (preliminary analysis). The left plot demonstrates that with a range of redshifts from 0.4 to 0.85, the approximately straight slope of the confidence region at a given redshift begins to rotate, allowing an intersection region (shown in green) to isolate measurements of  $\Omega_M$  and  $\Omega_\Lambda$  separately, not just in linear combination (see Goobar & Perlmutter, Ap.J. 1995). With the larger sample of supernovae shown on the right plot, the statistical uncertainty is now small enough—and the confidence regions narrow enough—that the systematic uncertainty is the dominant source of error. The dashed-line confidence region on the right plot shows our preliminary estimate of this systematic uncertainty (shown in the direction of 0.2 lower apparent magnitudes for the high redshift supernovae). Further analysis should reduce this uncertainty. The best-fit confidence region (in green on the right plot) is centered at  $\Omega_M = 0.5$ ,  $\Omega_\Lambda = 1.0$ . This confidence region lies along the line of  $\Omega_\Lambda = \Omega_M + 0.5$ , which is not parallel to the lines of constant deceleration  $q_0 = \Omega_M/2 - \Omega_\Lambda$ . Note that the confidence regions do not include the “standard model” inflationary universe with no cosmological constant (shown as a green circle at the intersection of the flat-universe line and the  $\Lambda = 0$  line). The confidence regions do suggest that we live in a universe that will expand forever.

# FLATNESS PROBLEM

# HORIZONS

The black solid lines indicate our present position. The blue line is the particle horizon through time, the red line is the event horizon, the green area is the Hubble sphere. The dotted black line is a co-moving galaxy that is currently located on the Hubble radius. Its photons that we observe today have travelled on the cyan path (they were emitted at  $t=4.3$  Gy). Its photons that it emits today ( $t=13.8$  Gy) will travel on the purple path (they will reach us at  $t=49$  Gy).
